

# CalDAV integration design questions

I am getting a fairly clear sense of how CalDAV clients and servers communicate with each other. I even read [the spec!](#) (Interesting aside, one of the primary authors of the CalDAV specification is Lisa Dusseault, who is a star character in "Dreaming in Code," the story of the Chandler project. She comes across as the smartest and sanest person on the team).

Here are the design questions I am currently mulling:

- Will the calendar store be configured Sakai-wide, per worksite, or per user per worksite?
- How should the configuration be done?
- How do we map between Sakai users and calendar server users?
- What happens with a Sakai guest user who may not have a calendar server identity?
